#### **Processes**

Chapter 3

### **Process Concept**

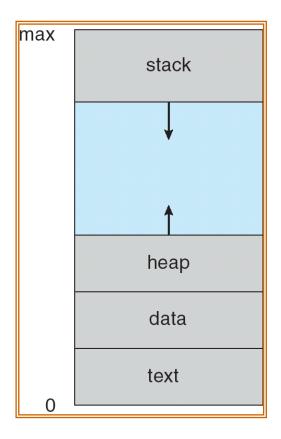

- An operating system executes a variety of programs:
  - Batch system jobs
  - Time-shared systems user programs or tasks
- the terms job and process are used almost interchangeably

### **Process in Memory**

 Process – a program in execution; process execution must progress in sequential fashion

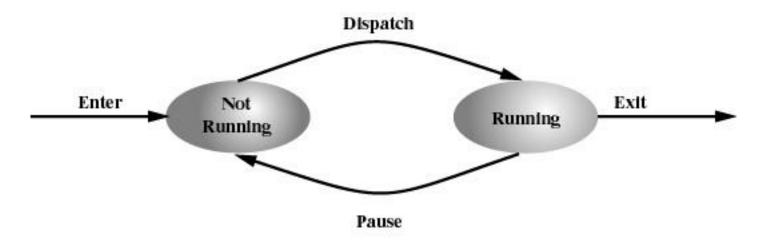

#### A process includes:

- program counter
- stack

#### **Two-State Process Model**

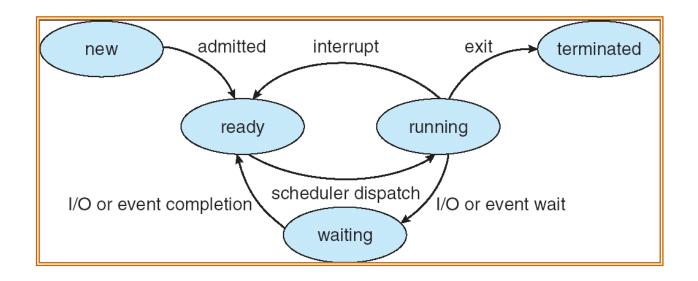

- Process may be in one of two states
  - Running
  - Not-running

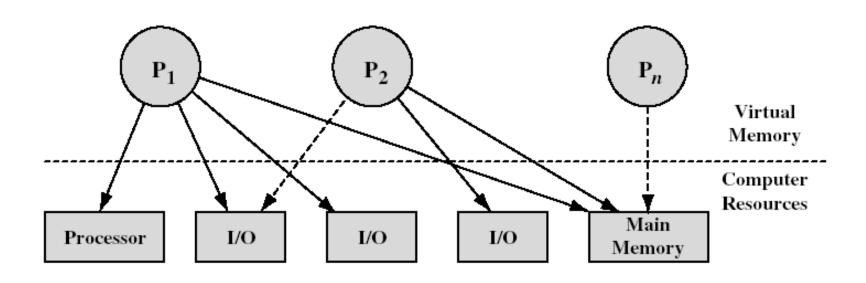

#### A Five-State Model

- As a process executes, it changes state
  - new: The process is being created
  - running: Instructions are being executed
  - Waiting (Blocked): The process is waiting for some event to occur
  - ready: The process is waiting to be assigned to a processor
  - terminated: The process has finished execution

### **Diagram of Process State**

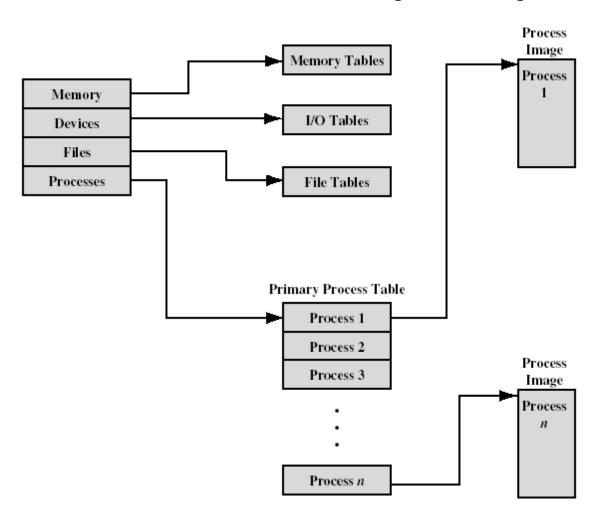

### **Process Description**

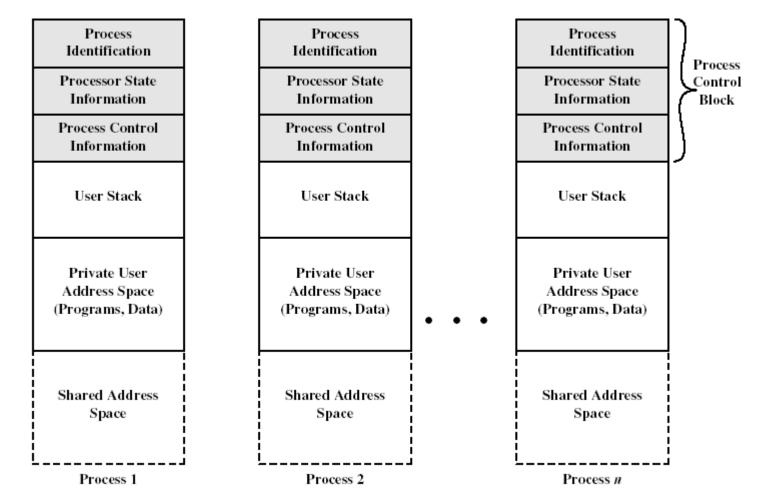

# Operating System Control Structures

- Information about the current status of each process and resource
- Tables are constructed for each entity the operating system manages

# Operating System Control Structures (cont.)

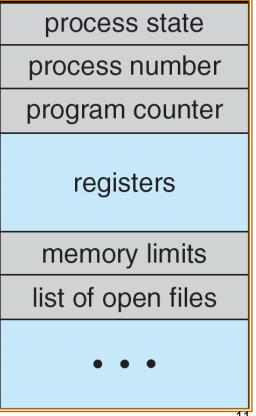

# User Processes in Virtual Memory

# **Process Control Block (PCB)**

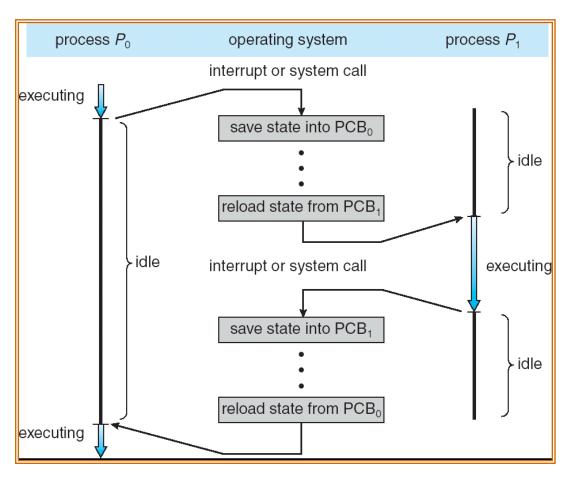

- Information associated with each process
  - Process state
  - Program counter
  - CPU registers
  - CPU scheduling information
  - Memory-management information
  - Accounting information
  - I/O status information

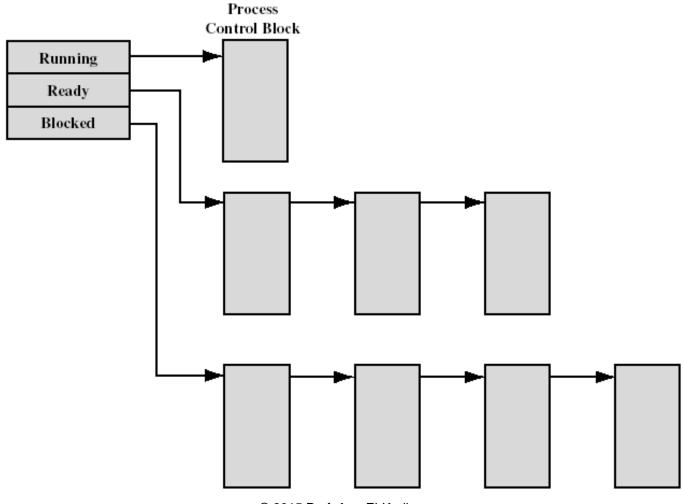

#### **Context Switch**

- When CPU switches to another process, the system must save the state of the old process and load the saved state for the new process
- Context-switch time is overhead; the system does no useful work while switching
- Time dependent on hardware support

# CPU Switch From Process to Process

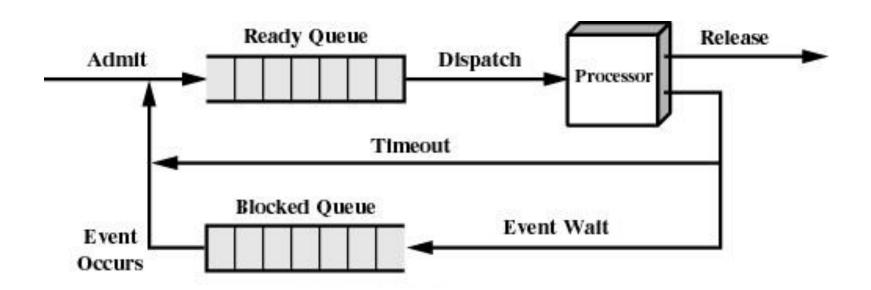

# The Role of the Process Control Block

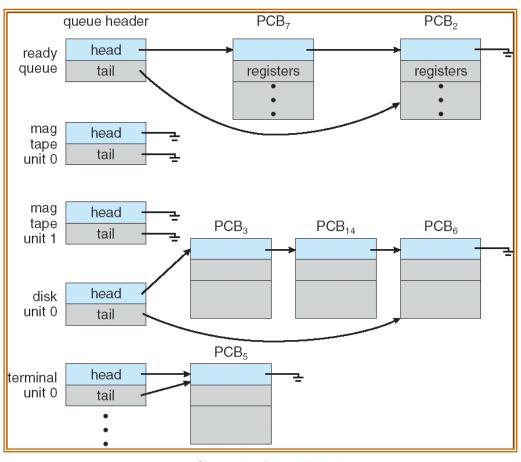

## **Process Scheduling Queues**

- Job queue set of all processes in the system
- Ready queue set of all processes residing in main memory, ready and waiting to execute
- Device queues set of processes waiting for an I/O device
- Processes migrate among the various queues

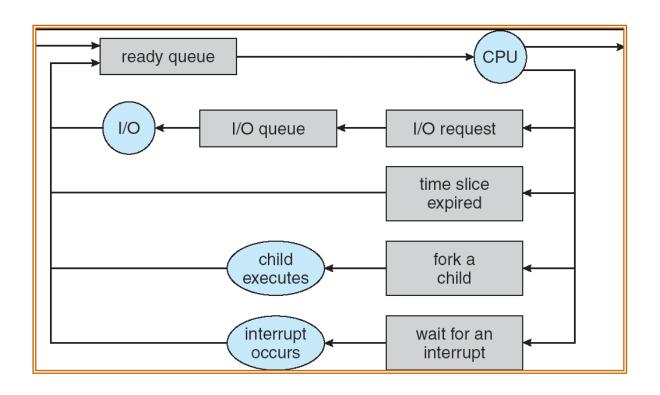

# **Using Two Queues**

# Ready Queue And Various I/O Device Queues

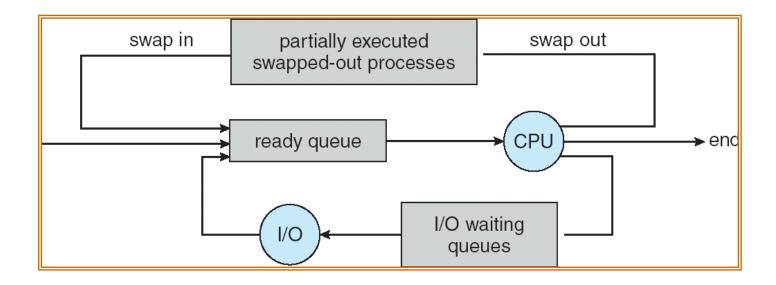

# Representation of Process Scheduling

#### **Schedulers**

- Long-term scheduler (or job scheduler) – selects which processes should be brought into the ready queue
- Short-term scheduler (or CPU scheduler) – selects which process should be executed next and allocates CPU

# Addition of Medium Term Scheduling

# Schedulers (Cont.)

- Short-term scheduler is invoked very frequently (milliseconds) ⇒ (must be fast)
- Long-term scheduler is invoked very infrequently (seconds, minutes) ⇒ (may be slow)
- The long-term scheduler controls the degree of multiprogramming

# Schedulers (Cont.)

- I/O-bound process spends more time doing I/O than computations, many short CPU bursts
- CPU-bound process spends more time doing computations; few very long CPU bursts

# Process Control: Modes of Execution

- User mode
  - Less-privileged mode
  - User programs typically execute in this mode
- System mode, control mode, or kernel mode
  - More-privileged mode
  - Kernel of the operating system

#### **Process Creation**

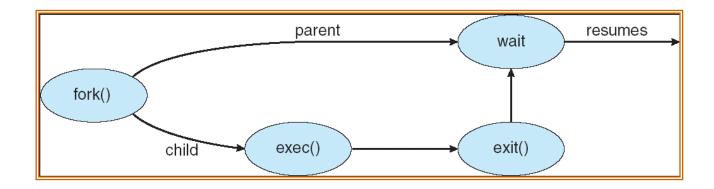

- Parent process create children processes, which, in turn create other processes, forming a tree of processes
- Resource sharing
  - Parent and children share all resources
  - Children share subset of parent's resources
  - Parent and child share no resources

## **Process Creation (Cont.)**

#### Execution

- Parent and children execute concurrently
- Parent waits until children terminate
- Address space
  - Child duplicate of parent
  - Child has a program loaded into it
- UNIX examples
  - fork system call creates new process
  - exec system call used after a fork to replace the process' memory space with a new program

#### **Process Creation**

#### **Process Creation in POSIX**

```
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>
int main()
pid_t pid;
   /* fork a child process */
   pid = fork();
   if (pid < 0) { /* error occurred */
      fprintf(stderr, "Fork Failed");
      exit(-1):
   else if (pid == 0) { /* child process */
      execlp("/bin/ls","ls",NULL);
   else { /* parent process */
      /* parent will wait for the child to complete */
      wait(NULL);
      printf("Child Complete");
      exit(0):
```

#### **Process Termination**

- Process executes last statement and asks the operating system to delete it (exit)
  - Output data from child to parent (via wait)
  - Process' resources are deallocated by operating system

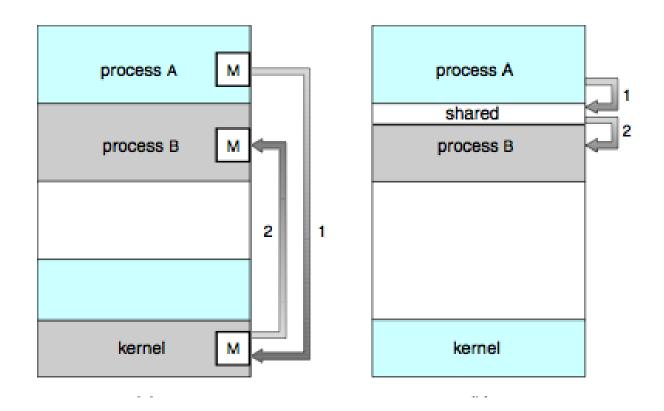

### **Process Termination (cont.)**

- Parent may terminate execution of children processes (abort)
  - Child has exceeded allocated resources
  - Task assigned to child is no longer required
  - If parent is exiting
    - Some operating system do not allow child to continue if its parent terminates
      - All children terminated cascading termination

## Interprocess Communication

#### Message Passing

#### **Shared Memory**

### **Cooperating Processes**

- Independent process cannot affect or be affected by the execution of another process
- Cooperating process can affect or be affected by the execution of another process
- Advantages of process cooperation
  - Information sharing
  - Computation speed-up
  - Modularity
  - Convenience

#### **Producer-Consumer Problem**

- Paradigm for cooperating processes, producer process produces information that is consumed by a consumer process
  - unbounded-buffer places no practical limit on the size of the buffer
  - bounded-buffer assumes that there is a fixed buffer size

# **Bounded-Buffer – Shared-Memory Solution**

 Shared data #define BUFFER SIZE 10 typedef struct { } item; item buffer[BUFFER\_SIZE]; int in = 0; int out = 0;

 Solution is correct, but can only use BUFFER\_SIZE-1 elements

# **Bounded-Buffer – Shared-Memory Solution**

```
public interface Buffer
{
    // producers call this method
    public abstract void insert(Object item);

    // consumers call this method
    public abstract Object remove();
}
```

# **Bounded-Buffer – Shared-Memory Solution**

```
public class BoundedBuffer implements Buffer
   private static final int BUFFER_SIZE = 5;
   private int count; // number of items in the buffer
   private int in; // points to the next free position
   private int out; // points to the next full position
   private Object[] buffer;
   public BoundedBuffer() {
     // buffer is initially empty
      count = 0:
      in = 0;
      out = 0:
      buffer = new Object[BUFFER_SIZE];
   // producers calls this method
   public void insert(Object item) {
      // Figure 3.16
   // consumers calls this method
   public Object remove() {
      // Figure 3.17
```

#### **Bounded-Buffer -- insert() method**

```
public void insert(Object item) {
   while (count == BUFFER_SIZE)
      ; // do nothing -- no free buffers

   // add an item to the buffer
   ++count;
   buffer[in] = item;
   in = (in + 1) % BUFFER_SIZE;
}
```

#### Bounded-Buffer - remove() method

```
public Object remove() {
  Object item;
  while (count == 0)
       ; // do nothing -- nothing to consume
  // remove an item from the buffer
  --count;
  item = buffer[out];
  out = (out + 1) % BUFFER_SIZE;
  return item;
```

#### Interprocess Communication – Message Passing

- Mechanism for processes to communicate and to synchronize their actions
- Message system processes communicate with each other without resorting to shared variables
- IPC facility provides two operations:
  - send(message) message size fixed or variable
  - receive(message)
- If P and Q wish to communicate, they need to:
  - establish a communication link between them
  - exchange messages via send/receive
- Implementation of communication link
  - physical (e.g., shared memory, hardware bus)
  - logical (e.g., logical properties)

### Implementation Questions

- How are links established?
- Can a link be associated with more than two processes?
- How many links can there be between every pair of communicating processes?
- What is the capacity of a link?
- Is the size of a message that the link can accommodate fixed or variable?
- Is a link unidirectional or bi-directional?

#### **Direct Communication**

- Processes must name each other explicitly:
  - send (P, message) send a message to process P
  - receive(Q, message) receive a message from process Q
- Properties of communication link
  - Links are established automatically
  - A link is associated with exactly one pair of communicating processes
  - Between each pair there exists exactly one link
  - The link may be unidirectional, but is usually bidirectional

#### **Indirect Communication**

- Messages are directed and received from mailboxes (also referred to as ports)
  - Each mailbox has a unique id
  - Processes can communicate only if they share a mailbox
- Properties of communication link
  - Link established only if processes share a common mailbox
  - A link may be associated with many processes
  - Each pair of processes may share several communication links
  - Link may be unidirectional or bi-directional

#### **Indirect Communication**

- Operations
  - create a new mailbox
  - send and receive messages through mailbox
  - destroy a mailbox
- Primitives are defined as:

**send**(*A, message*) – send a message to mailbox A

**receive**(*A, message*) – receive a message from mailbox A

#### **Indirect Communication**

#### Mailbox sharing

- $-P_1$ ,  $P_2$ , and  $P_3$  share mailbox A
- $-P_1$ , sends;  $P_2$  and  $P_3$  receive
- Who gets the message?

#### Solutions

- Allow a link to be associated with at most two processes
- Allow only one process at a time to execute a receive operation
- Allow the system to select arbitrarily the receiver.
   Sender is notified who the receiver was.

### **Synchronization**

- Message passing may be either blocking or non-blocking
- Blocking is considered synchronous
  - Blocking send has the sender block until the message is received
  - Blocking receive has the receiver block until a message is available
- Non-blocking is considered asynchronous
  - Non-blocking send has the sender send the message and continue
  - Non-blocking receive has the receiver receive a valid message or null

## **Buffering**

- Queue of messages attached to the link; implemented in one of three ways
  - Zero capacity 0 messages
     Sender must wait for receiver (rendezvous)
  - Bounded capacity finite length of n messages
     Sender must wait if link full
  - Unbounded capacity infinite length Sender never waits
